Assigned Question:

Q22. Debugging Bubble Sort Code (Missing Early Termination Optimization)

The following Bubble Sort code eventually produces the correct output, but it performs unnecessary passes even when the array becomes sorted early. Carefully analyze the existing implementation and identify the inefficiency in loop execution. Apply debugging and optimization techniques to introduce a flag-based termination mechanism. Explain how this optimization improves the practical performance of the algorithm. Analyze the corrected version in best, average, and worst cases. Rewrite the final optimized code with proper comments and readable structure.

```
def bubble_sort(arr):  
    n = len(arr)  
    for i in range(n):  
        for j in range(0, n-i-1):  
            if arr[j] > arr[j+1]:  
                arr[j], arr[j+1] = arr[j+1], arr[j]  
    return arr
```

Solution:

1. Missing Early Termination Optimization

Given Code:

```
for i in range(n):
```

Mistake:

- * The algorithm continues all passes even after the array becomes sorted.
- * This causes unnecessary comparisons and increases execution time.

Correction:

```
swapped = False
```

2. Missing Early Termination Condition**Given Code:**

```
for i in range(n):
```

Mistake:

- * The algorithm does not check whether any swapping occurred during a pass.
- * Even if the array is already sorted, it continues executing the remaining passes.

Correction:

```
for i in range(n):
```

```
    swapped = False
```

3. Missing Swap Tracking**Given Code:**

```
if arr[j] > arr[j + 1]:
```

```
    arr[j], arr[j + 1] = arr[j + 1], arr[j]
```

Mistake:

- * The code swaps elements correctly but does not record whether a swap has occurred.
- * Without tracking swaps, the algorithm cannot terminate early.

Correction:

```
if arr[j] > arr[j + 1]:
```

```
    arr[j], arr[j + 1] = arr[j + 1], arr[j]
```

```
    swapped = True
```

4. Missing Break Statement**Mistake:**

- * The algorithm performs unnecessary passes even when no elements are exchanged.
- * This reduces the practical performance of Bubble Sort.

Correction:

if not swapped:

```
    break
```

5. Readability Improvements

- * Add comments explaining each step.
- * Use proper indentation.
- * Use meaningful variable names.
- * Keep the code simple and readable.

After correction:

```
1- def bubble_sort(arr):
2
3     # Find the length of the array
4     n = len(arr)
5
6     # Traverse through all passes
7     for i in range(n):
8
9         # Assume no swapping in this pass
10        swapped = False
11
12        # Compare adjacent elements
13        for j in range(0, n - i - 1):
14
15            # Swap if elements are in the wrong order
16            if arr[j] > arr[j + 1]:
17                arr[j], arr[j + 1] = arr[j + 1], arr[j]
18
19            # Mark that a swap has occurred
20            swapped = True
21
22        # Stop if no swaps occurred
```

Original Array : [64, 34, 25, 12, 22, 11, 90]
Sorted Array : [11, 12, 22, 25, 34, 64, 90]
=== Code Execution Successful ===

Why the Optimization Improves Performance

The optimized Bubble Sort uses a swapped flag to detect whether any exchange occurs during a pass. If no elements are swapped, the array is already sorted. The algorithm terminates immediately instead of executing the remaining passes. This reduces unnecessary comparisons and improves the practical performance of Bubble Sort.

Time Complexity

- Best Case: $O(n)$
- Average Case: $O(n^2)$
- Worst Case: $O(n^2)$
- Space Complexity: $O(1)$
